Executive Strategic Brief: NovaTech Revenue Operations BI Framework

Prepared for: Sarah Chen, VP of Revenue Operations
Prepared by: Ezekiel Kimani, Lead Revenue Operations Analyst
Date: September 15, 2026

1. Data Strategy and Dashboard Design

To provide a reliable view of revenue operations, we combined sales opportunity data, marketing signup records, and customer support complaints in Amazon QuickSight. The data is stored in **SPICE (Super-fast, Parallel, In-memory Calculation Engine)**, which allows QuickSight to access prepared data quickly. The final dataset contains **63,420 rows, with 100% successfully loaded**.

The sales pipeline was retained as the main dataset when the sources were combined. A **left join**, which keeps all records from the main dataset even when related information is missing, was used to avoid losing active sales opportunities or revenue records. Because one account can have multiple support complaints, we also configured the data to prevent repeated records from overstating financial results.

The final dashboard has three pages, each beginning with a key performance indicator (KPI) so leadership can see the main result before reviewing supporting detail.

-

Marketing Funnel Analysis: Highlights **63,420 processed lead signups**, with charts showing signup sources and campaign performance.

-
-

Sales Pipeline Management: Highlights **$239,538,209.23** in total sales value, with views of revenue by company size and reasons for lost deals.

-
-

Customer Health Matrix: Highlights **2,792 unique post-sale support complaints**, with views connecting account revenue to support activity and operational priority.

-

2. QuickSight Q Accuracy and Topic Configuration

We tested QuickSight Q, the conversational feature that allows users to ask questions about the data in everyday language. Initially, Q did not always understand the business meaning of terms such as revenue and revenue risk. For example, when asked which campaign generated the most revenue, it counted records and returned **17.93K** instead of calculating the revenue value. It also interpreted “worst revenue risks” as smaller dollar amounts rather than high-value customers experiencing serious support problems.

We improved the **Topic**, which defines how Q understands the available data, by removing duplicate fields, setting appropriate field properties, and adding business synonyms. Revenue fields were linked to terms such as **revenue, contract value, and deal size**, while complaint measures were linked to **support load and revenue risk**.

After the changes, Q correctly identified the leading campaign at **$108.78M**, matching the dashboard result. This demonstrated that better Topic configuration improved the accuracy of conversational analysis.

3. AI Findings Compared with the Dashboard

Q agreed with the dashboard when questions involved clearly defined measures. For example, it correctly identified **ACCT-012 with 8.28K support tickets** and **ACCT-041 with 5,010 tickets**, matching the manual dashboard analysis.

However, Q could not answer questions requiring calculations that had not been defined in the available data. It could not identify the highest conversion rate because that measure required a calculation not present in the source data. It also could not determine whether campaigns spent more than they earned because campaign costs were not available for the analysis. **ROI (Return on Investment)** is a measure of the value generated compared with the money spent.

The testing therefore shows that Q is useful for quick questions about well-defined measures, while the structured dashboards remain more suitable for complex analysis and strategic decisions.

4. Key Insights and Recommended Actions

Sales: The mid-size Professional tier generates **more than $58M** in total value. However, **Budget Constraints account for 42% of sales attrition across 22.99K lost deals**, making them the largest identified barrier to closing sales.

Recommended action: Consider flexible, tiered quarterly payment options for suitable customers to reduce budget-related barriers at the closing stage.

Customer Health: ACCT-041 represents approximately $58M in revenue and has recorded **5,010 support complaints**, concentrated mainly around the software's pop-up alerts module. The combination of high revenue value and persistent technical problems creates a significant retention risk.

Recommended action: Assign a senior technical support team and an executive supervisor to ACCT-041 within **48 hours**, with immediate focus on resolving the pop-up alerts problems and maintaining direct communication with the customer.

Conclusion

The completed BI framework provides a consistent view of marketing, sales, and customer health. The analysis confirms that properly configured AI can support fast, accurate answers for defined measures, but it should complement rather than replace structured dashboards when deeper calculations are required. The immediate priorities are to reduce budget-related sales losses and protect the high-value ACCT-041 account.
